Abstract

It was recently found that the decay of inflaton and the SUSY breaking field produces many gravitinos in the gravity mediation scenario. These discoveries led to an exclusion of many inflation models such as chaotic, (smooth) hybrid, topological and new inflation models. Under these circumstances we searched for a successful inflation model and found that the “inverted” hybrid inflation models can solve the gravitino overproduction problem by their distinctive shape of the potential. Furthermore, we found that this inflation model simultaneously can explain the observed baryon asymmetry through the non-thermal leptogenesis and is consistent with the WMAP results, that is, $n_s = 0.951^{+0.015}_{-0.019}$ and the negligible tensor to scalar ratio.

1 Introduction

Supersymmetric standard model has been considered as the most promising candidate of the beyond standard model. In this model, the large gauge hierarchy and the observed dark matter density are explained and the gauge coupling unification is realized. It is also considered that the inflationary era [1] must exist in the very early universe. Many cosmological problems such as the flatness and the horizon problems can be solved by the presence of the inflationary era. Furthermore, the observed almost scale invariant spectrum of CMB [2] is also explained by the flat potential of the inflaton.

However, it was recently found that many inflation models are not compatible with the supersymmetric standard models, since the gravitinos are overproduced by the inflaton decay [3]. Especially in the gravity mediation scenario, the situation is disastrous, since the neutrality of the SUSY breaking field makes the inflaton decay rate into a pair of gravitinos larger. Furthermore, the neutrality causes an overproduction of the SUSY breaking fields which mainly decay into gravitinos [4]. By the study of these effects, it was revealed that most of the known inflation models, that is, chaotic, hybrid, topological and new inflation models are disfavored in the gravity mediation scenario [3, 4, 5, 6, 7, 8].

In this paper, we try to solve these problems without severe fine tunings. As solutions, we have two alternatives in principal, that is, (i) changing the hidden sector and (ii) constructing a successful inflation model ¹. In this paper, we focus on the second alternative, since the first alternative is not effective for the generic gravity mediation scenarios and it was already tried in [9], which showed that the gravitino problem can be avoided in a specific tuned gravity mediation model. We also examine whether the inflation model is compatible with the observed red tilted spectrum and accommodates the successful baryogenesis mechanism which is a necessary ingredient in the present universe. As a result, we find that inverted hybrid inflation models [10] can solve the all cosmological problems without any fine tunings.

The organization of this paper is as follows. In section 2 we briefly explain the cosmological problems of inflation models assuming that SUSY breaking is mediated by Planck suppressed operators and gravitinos are unstable. In section 2.1, we explain the gravitino

¹Surely we have a third alternative in which an exotic sector is added only for the solution. However, we do not consider this alternative, since it does not seem to be a minimal solution.

overproduction problem by the decay of the SUSY breaking field and a successful solution for this problem. We explain the gravitino production by the decay of inflaton and other gravitino sources in section 2.2 and 2.3 respectively. In section 3, we study an inverted hybrid inflation model and show that this inflation model solves the gravitino overproduction problems and accommodates the leptogenesis scenario. Finally, we summarize our results in section 4.

2 Cosmological Problems in Gravity Mediation

It was recently revealed that the gravitinos can be overproduced by the decay of the SUSY breaking field, inflaton and other sources in the gravity mediation scenario. Here we briefly explain the generality of this problem and summarize the constraints which we study in section 3. See [4, 5] for details of this problem.

2.1 Cosmological problem of SUSY breaking field

2.1.1 Polonyi problem

In the gravity mediation scenario, it is inevitable that the SUSY breaking field has a very small mass $\sim O(100)$ GeV and a very large amplitude $\sim O(M_{\text{pl}})$ after the primordial inflation, if the cut-off scale of the theory is the Planck scale. These two features together cause a serious cosmological problem called Polonyi problem [11]. Let us verify these two features and their implications for the cosmology.

In SUGRA, a “Chirality-flipped mass matrix” M_{ij}^2 at the vacuum with zero cosmological constant can be written in terms of the total Kähler potential, $G = K + \ln |W|^2$, as

$$M_{ij}^2 \equiv \left\langle \frac{\partial^2 V}{\partial \phi^i \partial \phi^{j*}} \right\rangle = m_{3/2}^2 \langle \nabla_i G_k \nabla_{j*} G^k - R_{ij*kl*} G^k G^{l*} + g_{ij*} \rangle, \quad (1)$$

where $m_{3/2}$ denotes the gravitino mass, the subscripts i denotes a derivative with respect to the field ϕ^i , and superscript is raised by g^{ij*} which is an inverse matrix of the Kähler metric g_{ij*} ². The curvature of the Kähler manifold R_{ij*kl*} is defined by $R_{ij*kl*} \equiv g_{ij*kl*} - g^{mn*} g_{mj*l*} g_{n*ik}$. The covariant derivative is defined by $\nabla_i G_j \equiv \partial_i G_j - \Gamma_{ij}^k G_k$, where $\Gamma_{jk}^i \equiv g^{kl*} g_{ijl*}$ is the connection.

² In this paper, we take the unit with the reduced Planck scale $M_{\text{pl}} \simeq 2.4 \times 10^{18} \text{GeV}$ equal to one, unless we explicitly denote.

Potential minimization condition $\langle V_i \rangle = 0$ is also written as

$$\langle G^j \nabla_i G_j + G_i \rangle = 0, \quad (2)$$

which leads to an inequality:

$$|G^j G_{ij}| = |g^{kl*} g_{ijl*} G^j G_k + G_i| < O(1). \quad (3)$$

In the last inequality, we have used inequalities $G_i \lesssim O(1)$ ³ and an assumption that a cut-off scale of the theory is the Planck scale, that is, all higher dimensional operators in the Kähler potential are only divided by the Planck scale.

Using $G_Z \simeq \sqrt{3}$ and Eq.(3), inequalities for the SUSY breaking field Z are given by:

$$|G_{iZ}| \lesssim O(1), \quad (4)$$

if cancellations do not occur in the left hand side of Eq.(3).

Thus we can estimate an upper bound of the “Chirality-flipped mass” of the SUSY breaking field as

$$M_{zz^*}^2 \lesssim m_{3/2}^2, \quad (5)$$

where we have used $R_{ij^*kl^*}, g_{ij^*} \lesssim 1$ which come from the assumption that the cut-off scale is the Planck scale. Moreover, “Chirality-conserving mass” M_{zz}^2 must be smaller than the “Chirality-flipped mass” $M_{zz^*}^2$, since the potential becomes tachyonic otherwise. Thus we have verified that the SUSY breaking field is always lighter than the gravitino, when the cut-off scale of the theory is the Planck scale.

Now, let us consider the initial amplitude of the SUSY breaking field Z . The amplitude is determined by the potential of Z during the primordial inflation which is controlled by the charge of the SUSY breaking field Z . Here note that the SUSY breaking field must be neutral for any symmetry, since the MSSM gaugino masses are given by operators $\int d^2\theta \frac{Z}{M_{\text{Pl}}} W^\alpha W_\alpha$, where W^α denote the gauge field strength chiral superfields.

This neutrality of the SUSY breaking field implies that we cannot forbid a linear term of the SUSY breaking field in the Kähler potential:

$$K(Z) = c_0^\dagger Z + c_0 Z^\dagger + |Z|^2 + \dots, \quad (6)$$

³ The inequalities $G_i \lesssim O(1)$ are required for the very small cosmological constant which is proportional to $(G^i G_i - 3)$ in SUGRA.

where c_0 is a dimensionful parameter and expected to be of the order of the Planck scale. Furthermore, even if some unknown mechanism at the Planck scale suppresses the coefficient at the tree-level, a linear term with $c_0 \gtrsim O(N_g/16\pi^2)M_{\text{pl}}$ is generated through 1-loop diagrams in which N_g MSSM gauge multiplets circulate. Thus we must consider that the coefficient of the linear term is at least of order $0.1M_{\text{pl}}$, i.e. $|c_0| \gtrsim 0.1M_{\text{pl}}$. Note that it contrasts with the FCNC constraints, where the dangerous flavor changing operators are not induced, if these operators are suppressed at the Planck scale.

By using this Kähler potential $K(Z)$ and a potential of the inflaton V_{inf} which is nearly constant during the inflation, the potential of the SUSY breaking field during the inflation is approximately written as

$$\begin{aligned}
V(Z) &= e^K |W|^2 (G_i G^i - 3) \\
&\simeq e^{K(Z)} V_{\text{inf}} + m_Z^2 |Z|^2 \\
&\simeq 3e^{K(Z)} H_{\text{inf}}^2 + m_Z^2 |Z|^2 \\
&\simeq 3H_{\text{inf}}^2 (c_0^\dagger Z + c_0 Z^\dagger) + (3H_{\text{inf}}^2 + m_Z^2) |Z|^2 + \dots,
\end{aligned} \tag{7}$$

where m_Z denotes the mass of the SUSY breaking field and H_{inf} is the Hubble constant during the primordial inflation. In the third equality, we have used a Friedmann equation during the inflation $V_{\text{inf}} \simeq 3H_{\text{inf}}^2$. Thus we can verify that the SUSY breaking field have a large initial amplitude $\Delta Z \simeq c_0 \gtrsim 0.1M_{\text{pl}}$ after the inflation and the universe is dominated by the SUSY breaking field with the large initial amplitude. Here we have assumed an inequality $H_{\text{inf}} > m_{3/2} \simeq O(100)\text{GeV} \gtrsim m_Z$, which is satisfied in most inflation models.

In the gravity mediation scenario, the SUSY breaking fields interact with the visible sectors only by Planck suppressed operators. Thus the decay time $\tau_Z \gtrsim M_{\text{pl}}^2/m_Z^3 \gtrsim M_{\text{pl}}^2/m_{3/2}^3$ is much longer than the timescale of the nucleosynthesis $\simeq O(1)$ sec for the typical gravitino mass range $\simeq O(100)\text{GeV}$. Such a late time decay of the SUSY breaking field with too large number density spoils the prediction of the Big Bang nucleosynthesis. This serious cosmological problem in the gravity mediation scenario is called Polonyi problem [11]⁴.

⁴ Note that the SUSY breaking field has serious cosmological problem, even if its mass is rather large $m_Z \simeq O(10)\text{TeV}$ [12].

2.1.2 Solution: Dynamical SUSY breaking and low scale inflation models

The Polonyi problem seems to be solved, if a condition $m_Z \gg m_{3/2}$ is satisfied and the SUSY breaking field decays rapidly. One way to realize this situation is to violate the assumption that all higher dimensional operators are only divided by the Planck scale. For example, by introducing a higher dimensional operator $|Z|^4/M'^2 \gg |Z|^4/M_{\text{pl}}^2$ into the Kähler potential, a large mass term for the SUSY breaking field is induced as

$$V \supset \frac{|F_Z|^2}{1 - \frac{|Z|^2}{M'^2} + \dots} \sim \frac{\Lambda^4}{M'^2} |Z|^2 + \dots \gg m_{3/2}^2 |Z|^2, \quad (8)$$

where $\Lambda = \sqrt{F_Z} = 3^{1/4} \sqrt{m_{3/2} M_{\text{pl}}}$ denotes the SUSY breaking scale.

We can have such a higher dimensional operator $|Z|^4/\Lambda^2$ in the Kähler potential by nonperturbative effects, when SUSY is dynamically broken⁵. Furthermore, the electroweak scale is explained by the dimensional transmutation in this case. Thus it seems that the Polonyi problem is solved when the electroweak scale is realized by the dynamical SUSY breaking models. However, in this solution we must constrain the energy scale of the inflation model.

First, let us consider the case $H_{\text{inf}} \gtrsim \sqrt{m_{3/2} m_Z} \simeq 10^7 \text{ GeV}$ ⁶. For a significantly modified potential by the large Hubble constant, the initial amplitude of the SUSY breaking field is larger than the dynamical scale Λ right after the inflation. As it is clear from the change of signature of the Kähler metric, for such a large field value the effective Kähler potential $K_{\text{eff}} \simeq |Z|^2 - |Z|^4/\Lambda^2 + \dots$ is not valid and the potential is very flat around the initial field value. Thus we suffer from the recurrence of the Polonyi problem for such a large Hubble constant [4].

Second, let us consider the case $H_{\text{inf}} \lesssim \sqrt{m_{3/2} m_Z}$. For this case, the initial amplitude is given by

$$\Delta Z = \frac{3H_{\text{inf}}^2}{m_Z^2} c_0 \lesssim \Lambda, \quad (9)$$

which does not cause the problem discussed in the last paragraph. However, there is a constraint on the yield of unstable gravitinos, and this gives an upper bound on H_{inf} .

⁵ There is Izawa-Yanagida-Intriligator-Thomas model [14] as an example of having such a higher dimensional operator.

⁶ This constraint depend on the SUSY braking model, although following discussions are not significantly changed. See [4] for a detailed discussion and a specific constraint in a model.

From the operator $|Z|^4/\Lambda^2$, a dimensionless coupling between the SUSY breaking field and the goldstinos arises as:

$$\int d^4\theta \frac{|Z|^4}{\Lambda^2} \supset \frac{F_Z^\dagger}{\Lambda^2} Z^\dagger \psi_Z \psi_Z = Z^\dagger \psi_Z \psi_Z, \quad (10)$$

which leads to a large decay width into gravitinos: $\Gamma(Z \rightarrow \psi_{3/2} \psi_{3/2}) \sim m_Z/8\pi$. For this decay width, the SUSY breaking field mainly decays into two gravitinos, whose lifetime is longer than the time scale of the nucleosynthesis. The yield of the gravitinos produced by the decay of the SUSY breaking field is

$$Y_{3/2}^{\text{Pol}} = \frac{T_R m_Z (\Delta Z)^2}{2H_{\text{inf}}^2} = \frac{9T_R H_{\text{inf}}^2}{2m_Z^3} c_0^2, \quad (11)$$

where T_R denotes the reheating temperature.

The observed light elements abundances give the following constraint on the yield of the unstable gravitinos [15, 16]:

$$Y_{3/2} \lesssim Y_{3/2}^{\text{upper}} \quad (12)$$

$$Y_{3/2}^{\text{upper}} = \begin{cases} 1 \times 10^{-16} - 5 \times 10^{-14} & \text{for } m_{3/2} \simeq 0.1 - 1 \text{ TeV} \\ 2 \times 10^{-14} - 5 \times 10^{-14} & \text{for } m_{3/2} \simeq 1 - 3 \text{ TeV} \\ 3 \times 10^{-14} - 2 \times 10^{-13} & \text{for } m_{3/2} \simeq 3 - 10 \text{ TeV} \end{cases} \quad (B_h \simeq 10^{-3}), \quad (13)$$

where B_h denotes the hadronic branching ratio, which is assumed to be 10^{-3} for conservative discussions in this paper. These observational constraints lead to a constraint on the Hubble scale during the inflation:

$$\begin{aligned} H_{\text{inf}} \lesssim H_{\text{inf}}^{\text{MAX}} &\equiv 1.5 \times 10^6 \text{ GeV} \left(\frac{m_Z}{10^{11} \text{ GeV}} \right)^{3/2} \left(\frac{10^6 \text{ GeV}}{T_R} \right)^{1/2} \left(\frac{M_{\text{pl}}}{c_0} \right) \left(\frac{Y_{3/2}^{\text{upper}}}{10^{-14}} \right)^{1/2} \\ &\lesssim 1.5 \times 10^7 \text{ GeV} \left(\frac{m_{3/2}}{\text{TeV}} \right)^{3/4} \left(\frac{10^6 \text{ GeV}}{T_R} \right)^{1/2} \left(\frac{M_{\text{pl}}}{c_0} \right) \left(\frac{Y_{3/2}^{\text{upper}}}{10^{-14}} \right)^{1/2}. \end{aligned} \quad (14)$$

In the last inequality, we have used an inequality $m_Z \lesssim \Lambda_{\text{dyn}} \sim 4\pi\Lambda$ ^{7, 8}.

This result shows that SUSY chaotic inflation [17, 18], SUSY topological inflation [19, 20, 21], and SUSY (smooth) hybrid inflation models [22, 23, 24, 25] are disfavored, since

⁷ Here, note that this constraint can not be loosened by decreasing the reheating temperature, since the yield of gravitinos produced through the inflaton decay becomes large for low reheating temperature. We will discuss this contribution in the next subsection.

⁸ Here we should note that the upper bound is close to the assumed constraint $H_{\text{inf}} \lesssim \sqrt{m_{3/2} m_Z}$. We must care whether the initial amplitude is smaller than the effective cut-off scale Λ in each SUSY breaking model, if the considering inflaton model has a energy scale close to the upper bound in Eq.(14).

the Hubble scale of these inflation models are determined from the observed anisotropy of CMB as:

$$H_{\text{inf}} = \begin{cases} 10^{14}\text{GeV} & \text{for Chaotic Inflation} \\ 10^{11-14}\text{GeV} & \text{for Topological Inflation} \\ 10^{13-15}\text{GeV} & \text{for (smooth) Hybrid Inflation} \end{cases} \quad (15)$$

On the contrary, some low scale inflation models can satisfy the constraint Eq.(14). For this reason, New inflation model ($H_{\text{inf}} \gtrsim 10^{5.4}\text{GeV}$) [26] and other low scale inflation models seem to be favored than the high scale inflation models in the gravity mediation scenario [4].

2.2 Gravitino overproduction through Inflaton direct decay

In this subsection, we review gravitino overproduction problem caused by the inflaton perturbative direct decay as another constraint in this paper ⁹ [3]. In spontaneously broken Super Gravity, the VEV of the inflaton is slightly shifted from that in the rigid case and mixing between inflaton and the SUSY breaking fields is nonzero, even if they do not directly couple in the Kähler or super potential. Thus the inflaton F-term, that is, the coupling with the gravitino is nonzero in SUGRA. Considering these effects, the inflaton decay width into the gravitinos is given by [27]

$$\Gamma(\phi \rightarrow 2\psi_{3/2}) = \frac{|G_{\phi}^{\text{eff}}|^2}{288\pi} \frac{m_{\phi}^5}{m_{3/2}^2 M_{\text{pl}}^2}, \quad (16)$$

where m_{ϕ} is the inflaton mass. And the effective coupling G_{ϕ}^{eff} is given by [28]

$$\begin{aligned} |G_{\phi}^{\text{eff}}|^2 &\simeq \left| \sqrt{3} g_{\phi z^*} \frac{m_z^2}{\text{Max}[m_{\phi}^2, m_z^2]} \right|^2 \\ &+ \left| \sqrt{3} (\nabla_{\phi} G_z) \frac{m_{3/2} m_z^2}{\text{Max}[m_{\phi}^2, m_z^2] m_{\phi}} \right|^2 + \left| 3 \frac{m_{3/2} m_{\phi}}{\text{Max}[m_{\phi}^2, m_z^2]} \right|^2. \end{aligned} \quad (17)$$

In the gravity mediation scenario, the effective coupling is much larger than that in the other mediation scenarios. In this scenario, the SUSY breaking field must be neutral for any symmetry, as we explained in section 2.1. For the neutrality of the SUSY breaking

⁹ In this topic, ‘*inflaton*’ denotes a scalar field whose coherent oscillation dominates the universe right after the inflation. Thus ‘*inflaton*’ in this topic is not necessarily the origin of the exponential expansion of the universe. For example, the waterfall fields in the Hybrid Inflation models correspond to this field.

field, the following mixing terms proportional to $c_i \sim O(1)$, $i = 1, \dots$ can not be forbidden by any symmetry like a linear term in Eq.(6). Thus the Kähler and super potential are written as

$$K = |\phi|^2 + |Z|^2 + |\phi|^2(c_1^\dagger Z + c_1 Z^\dagger) + \dots, \quad (18)$$

$$W = W_{\text{hid}} + W_{\text{inf}} + \sum_{i=2} c_i W_{\text{inf}}^{(i)} Z, \quad (19)$$

where W_{hid} , W_{inf} , $W_{\text{inf}}^{(i)}$ denote hidden, inflaton superpotential and each operators in the inflaton superpotential and the ellipses denote the other higher dimensional operators which may be dismissed in the following discussions.

For this Lagrangian the effective coupling G_ϕ^{eff} is approximately written as

$$\begin{aligned} |G_\phi^{\text{eff}}|^2 &\simeq \left| \sqrt{3} g_{\phi z^\dagger} \frac{m_z^2}{\text{Max}[m_\phi^2, m_z^2]} \right|^2 + \left| \sqrt{3} (\nabla_\phi G_z) \frac{m_{3/2}}{m_\phi} \frac{m_z^2}{\text{Max}[m_\phi^2, m_z^2]} \right|^2 \\ &\simeq 3|\phi|^2 \left(\frac{m_z^2}{\text{Max}[m_\phi^2, m_z^2]} \right)^2 \sum_{i=1} O(1) c_i^2 \\ &\equiv 3|\phi|^2 \left(\frac{m_z^2}{\text{Max}[m_\phi^2, m_z^2]} \right)^2 C^2, \end{aligned} \quad (20)$$

where $O(1)$ in the second line represent coefficients depending on inflation models¹⁰.

The yield of the gravitinos produced through the inflaton decay can be calculated by solving the Boltzmann equation. The solution is approximately written as:

$$\begin{aligned} Y_{3/2}^{\text{inf}} &\simeq 2 \frac{\Gamma(\phi \rightarrow 2\psi_{3/2})}{\Gamma_\phi} \frac{3T_R}{4m_\phi} \\ &\simeq 2.3 \times 10^{-6} \left(\frac{m_z^2}{\text{Max}[m_\phi^2, m_z^2]} \right)^2 \\ &\quad \times \left(\frac{\langle \phi \rangle}{10^{15} \text{GeV}} \right)^2 \left(\frac{m_\phi}{10^9 \text{GeV}} \right)^4 \left(\frac{10^7 \text{GeV}}{T_R} \right) \left(\frac{\text{TeV}}{m_{3/2}} \right)^2 C^2, \end{aligned} \quad (21)$$

where Γ_ϕ denotes the main decay width of the inflaton field.

This quantity must be smaller than the upper bound in Eq.(13):

$$Y_{3/2}^{\text{inf}} \lesssim Y_{3/2}^{\text{upper}}, \quad (22)$$

¹⁰ Here we neglected the third term in Eq.(17), since the contribution is much smaller than the other contributions in Eq.(20).

This constraint is so severe that (smooth) Hybrid Inflation is again disfavored for this reason [5]. Furthermore, New inflations model also become incredible¹¹. When Eq.(14) and (22) are simultaneously considered in New inflation models, severe fine tunings $c_i \lesssim 10^{-4}$ ($i = 0, 1, \dots$) are required for a constraint $Y_{3/2} < 10^{-14}$, even if the mass of the SUSY breaking field m_Z is appropriately tuned [8]. Thus it seems that New inflation models are also disfavored as well as chaotic, hybrid and topological inflation models.

2.3 Other contributions

Here, we mention contributions from the MSSM and hidden sector gauginos.

In SUGRA, all scalar fields including the inflaton field couple with the hidden gauge super multiplets by super Kähler-Weyl and σ -model anomalies [7]. This coupling induces a large decay width of the inflaton into the hidden gauge bosons and fermions, when the following condition is not satisfied:

$$m_\phi \lesssim m_{1/2}^{\text{hid}} \simeq \Lambda_{\text{dyn}} \simeq 4\pi\Lambda \simeq 10^{12}\text{GeV}, \quad (23)$$

where $m_{1/2}^{\text{hid}} \simeq \Lambda_{\text{dyn}}$ denotes the mass of the hidden gauge super multiplet. Since these fields finally decay into gravitinos, there can be a contribution comparable to Eq.(21), if the constraint Eq.(23) is violated. The gravitino yield is approximately given by [5]

$$Y_{3/2}^{\text{hid}} \simeq 9 \times 10^{-13} \xi \left(\frac{T_R}{10^6 \text{GeV}} \right)^{-1} \left(\frac{\langle \phi \rangle}{10^{15} \text{GeV}} \right)^2 \left(\frac{m_\phi}{10^{12} \text{GeV}} \right)^2, \quad (24)$$

where $\xi \simeq O(10^{-2}) - O(10)$ is a constant depending on the hidden sector. This yield must satisfy an inequality

$$Y_{3/2}^{\text{hid}} < Y_{3/2}^{\text{upper}}. \quad (25)$$

Thus the successful inflation model must satisfy the constraint Eq.(23) or (25).

There is also another well known source of gravitinos, that is, a contribution from thermal scatterings of MSSM gluinos [29]. This contribution $Y_{3/2}^{\text{th}}$ is written as:

$$Y_{3/2}^{\text{th}} \simeq 1.9 \times 10^{-12} \left[1 + \left(\frac{m_{\tilde{g}_3}^2}{3m_{3/2}^2} \right) \right] \left(\frac{T_R}{10^{10} \text{GeV}} \right)$$

¹¹ Note that this constraint can not be avoided by decreasing the mass of SUSY breaking field, since the contribution of Eq.(14) increases in that case.

$$\times \left[1 + 0.045 \ln \left(\frac{T_R}{10^{10} \text{GeV}} \right) \right] \left[1 - 0.028 \ln \left(\frac{T_R}{10^{10} \text{GeV}} \right) \right], \quad (26)$$

where $m_{\tilde{g}_3}$ is the gluino running mass evaluated at $\mu = T_R$. This quantity also must satisfy a condition

$$Y_{3/2}^{\text{th}} \lesssim Y_{3/2}^{\text{upper}}, \quad (27)$$

where $Y_{3/2}^{\text{upper}}$ is the same as that in Eq. (13).

Before closing this section, we summarize the constraints for successful inflation model. The gravitino sources and constraints are given as follows

- (i) **The SUSY breaking field Z :** If the Hubble constant during the inflation is too large, the decay of the SUSY breaking field produces too many gravitinos. This gravitino source gives the constraint Eq.(14) for inflation models.
- (ii) **Inflaton direct decay:** The gravitinos are also directly produced by the inflaton perturbative decay, when the inflaton field has non-vanishing VEV. Thus Eq.(22) must be satisfied in successful inflation models.
- (iii) **Gauge super multiplets in hidden sector:** If the inflaton field is heavier than the hidden gauge super multiplets, the decay of the inflaton produces these gauge bosons and fermions, whose decay can cause the gravitino overproduction. This overproduction can be avoided, if Eq.(23) or (25) is satisfied.
- (iv) **Thermal scatterings:** Thermal scatterings of gauginos in visible sector also produce the gravitinos. Since the gravitino yield is proportional to the reheating temperature, there is an upper bound for the reheating temperature which is given by Eq.(27).

In the gravity mediation scenario, it has been revealed that most of the known inflation models are disfavored on account of these four gravitino sources. In the next section, we will try to find a inflation model satisfying these constraints, and check whether the baryogenesis can be accommodated.

3 Solution to the Gravitino Overproduction problem

3.1 Inverted Hybrid inflation and its energy scales

In this section, we study inflation models consistent with the WMAP observation: $\delta\rho/\rho = 1.9 \times 10^{-5}$, $n_s = 0.951^{+0.015}_{-0.019}$ [2] and the constraints argued in section 2.

Inflation models consistent with the WMAP result can be classified by their shapes of the potentials as follows [30]:

$$V = \begin{cases} \lambda\phi^n & n \geq 2 \quad \text{Chaotic Inflation,} \\ V_0 \left[1 - \left(\frac{\phi}{\mu} \right)^p \right] & p \leq -2 \quad \text{Hybrid Inflation,} \\ V_0 \left[1 - \left(\frac{\phi}{\mu} \right)^p \right] & p \geq 2 \quad \text{New, Topological or Inverted Hybrid Inflation.} \end{cases} \quad (28)$$

Although all these inflation models can explain the WMAP results, these models except for “inverted” hybrid inflation models are disfavored as we saw in section 2. Thus we focus on studying whether there is an inverted hybrid inflation model satisfying the constraints in section 2 and generating the observed baryon asymmetry¹².

A successful Inverted Hybrid Inflation model must have sufficiently low height of the potential, a small VEV and a small mass of the waterfall field to suppress the gravitinos produced through the processes (i), (ii) and (iii). We expect that the constraints from (i), (ii), (iii), (iv), and the WMAP observations ($n_s \simeq 1 - 2k = 0.951^{+0.015}_{-0.019}$ and $V^{3/2}/V' \simeq v^2/ks_f \simeq 5.3 \times 10^{-4}$) are satisfied by a potential like in Fig. 3.1, if the reheating temperature takes an appropriate value $\simeq 10^6$ GeV. Here k is related to a coefficient of dimension 4 operator in the Kähler potential, $v \equiv V^{1/4}$ represents the height of the potential and s_f denotes a field value of the inflaton at the end of the inflation. We will explain the details of these parameters in a specific model.

This potential can be written as

$$V(s, \psi) = (v^2 - \frac{\lambda}{4}\psi^2)^2 + (A\sqrt{\lambda}v - \frac{g}{\sqrt{2}}s)^2 \frac{\psi^2}{2} - \frac{k}{2M_{\text{pl}}^2}v^4 s^2 + \frac{k'}{2M_{\text{pl}}^2}v^4 \psi^2, \quad (29)$$

¹² We are also interested in A-term inflation [34], since this inflation model also suppress the gravitinos produced through the processes (i), (ii), (iii) and (iv). However, we do not focus on this possibility in this paper, since it seems for us that all the baryogenesis mechanisms except for electroweak baryogenesis cannot work and the initial field value of the inflaton must be fine tuned in this set up.

Figure 1: This figure is an ideal potential of the inverted hybrid inflation model. In this potential the COBE normalization $V^{3/2}/V' \simeq v^2/(ks_f) \simeq 5 \times 10^{-4}$ can be satisfied by $v \sim 10^{10} \text{ GeV}$, $s_f \simeq 10^8 \text{ GeV}$ and $k \simeq O(0.01)$ (k is also determined from the spectral index n_s). When the reheating temperature takes an appropriate value $T_R \simeq 10^6 \text{ GeV}$, we can also avoid the gravitino overproduction induced by the processes (i), (ii), (iii) and (iv).

where s and ψ are real scalar fields, and the constants $v \simeq O(10^{10})\text{GeV}$, $\lambda \simeq O(10^{-5})$, $A > 1$, $g \simeq O(1)$, $k \simeq O(0.01)$ and k' are all real and positive ¹³.

In the inverted hybrid inflation model, the inflaton s and the waterfall field ψ are set to the origin at first by some mechanism ¹⁴. Then the inflaton field slowly rolls down to large field value, decreasing the coefficient of the second term in Eq.(29) which stabilizes ψ to the origin. Finally the inflation era ends by the ψ 's water-falling, when the inflaton s reaches to the waterfall point $s = s_f$, which is given by ¹⁵:

$$s_f = \frac{\sqrt{2\lambda}}{g}(A-1)v. \quad (30)$$

The value s_{N_e} of the inflaton corresponding to the e -fold number N_e is given by

$$N_e \simeq \int_{s_f}^{s_{N_e}} ds \frac{1}{M_{\text{pl}}^2} \frac{V(s, 0)}{V'(s, 0)} \simeq \int_{s_f}^{s_{N_e}} ds \frac{v^4}{-kv^4 s} = \frac{1}{k} \ln \left(\frac{s_f}{s_{N_e}} \right), \quad (31)$$

where $V'(s, 0)$ denotes a derivative by a inflaton field s . This leads to

$$s_{N_e} = e^{-kN_e} s_f = \frac{\sqrt{2\lambda}}{g}(A-1)ve^{-kN_e}. \quad (32)$$

Now let us determine the inflation scale v as a function of the other parameters. The amplitude of the primordial density fluctuations is given by

$$\frac{\delta\rho}{\rho} \simeq \frac{1}{5\sqrt{3}\pi M_{\text{pl}}^3} \frac{V^{\frac{3}{2}}(s_{N_0})}{|V'(s_{N_0})|} \simeq \frac{1}{5\sqrt{3}\pi} \frac{v^6}{kv^4 s_{N_0} M_{\text{pl}}}, \quad (33)$$

where s_{N_0} is the value of the inflaton field at the epoch of the present horizon exit. Thus the inflation energy scale $v = V^{\frac{1}{4}}$ is written as

$$v = k \frac{V^{\frac{3}{2}}}{V' M_{\text{pl}}^2} \sqrt{2\lambda} \left(\frac{A-1}{g} \right) e^{-kN_0}. \quad (34)$$

Owing to the COBE normalization

$$\frac{1}{M_{\text{pl}}^3} \frac{V^{\frac{3}{2}}(s_{N_0})}{|V'(s_{N_0})|} \simeq 5.3 \times 10^{-4}, \quad (35)$$

¹³ It seems that we have fine tuned λ in this model instead of c_i parameters. However, notice that tunings of superpotential couplings are technically natural and the coupling λ can be small by some symmetries in specific models. It is not the case for the c_i parameters.

¹⁴ This mechanism may be finite temperature effects or Hubble mass induced by a foregoing (chaotic) inflation. Anyway such mechanisms do not change the following results.

¹⁵ See [32] for a review of slow roll inflation and its prediction.

the scale v is expressed as

$$v \simeq 5.7 \times 10^{10} \text{GeV} \times \mathcal{C}(k, N_0) \times \frac{A-1}{g} \times \left(\frac{\lambda}{10^{-5}} \right)^{\frac{1}{2}}, \quad (36)$$

for e-fold $N_0 \simeq 40$ and $|k| \lesssim O(0.01)$, where $\mathcal{C}(k, N_0)$ is a function of order unity.

Then let us consider the spectral index n_s and the tensor to scalar ratio r . These values for the small field value $s_{N_0} \ll M_{\text{pl}}$ are approximately given by

$$n_s \simeq 1 + 2M_{\text{pl}}^2 \left(\frac{V''(s, 0)}{V(s, 0)} \right) \Big|_{s=s_{N_0}} \simeq 1 - 2k, \quad (37)$$

$$r \simeq 16 \times \frac{M_{\text{pl}}^2}{2} \left(\frac{V'(s, 0)}{V(s, 0)} \right)^2 \Big|_{s=s_{N_0}} \simeq 8k^2 \frac{s_{N_0}^2}{M_{\text{pl}}^2} \ll 1 \quad (38)$$

Thus the observed red tilted spectrum $n_s = 0.951_{-0.019}^{+0.015}$ and the negligible tensor to scalar ratio can be easily explained in the inverted hybrid inflation models. It is in contrast with the other hybrid inflation models.

The e-folding number N_0 corresponding to the present horizon is also given by

$$N_0 \simeq 67 + \frac{1}{3} \ln \frac{H_{\text{inf}}}{M_{\text{pl}}} + \frac{1}{3} \ln \frac{T_R}{M_{\text{pl}}} \simeq 67 + \frac{1}{3} \ln \frac{v^2}{\sqrt{3}M_{\text{pl}}^2} + \frac{1}{3} \ln \frac{T_R}{M_{\text{pl}}}, \quad (39)$$

where H_{inf} denotes a Hubble scale at the horizon exit and T_R the reheating temperature.

By means of Eqs. (36), (37) and (39), we can express inflation energy scale v and the Hubble constant H_{inf} by the couplings A , g , λ and the reheating temperature T_R . For $T_R \simeq 10^6 \text{GeV}$, the Hubble constant is approximately given by

$$H_{\text{inf}} \simeq 1.7 \times 10^7 \text{GeV} \times \lambda \left(\frac{A-1}{g} \right)^2. \quad (40)$$

Thus, the constraint Eq.(14) from the process (i) is satisfied for small λ , which can be controlled by some symmetries.

3.2 Reheating and Inverted hybrid inflation in SUGRA

In this subsection, we study the other constraints from the processes (ii), (iii) and (iv), which are strongly related to the SUGRA effects and the reheating process. Here we also take into account the baryogenesis mechanism which is a very important process after the inflation.

For these purposes, we examine a following model ¹⁶:

$$K = K_{\text{Pol}}^{(\text{eff})} + K_{\text{inf}} + K_{\text{int}} \quad (41)$$

$$W = W_{\text{Pol}}^{(\text{eff})} + W_{\text{inf}}. \quad (42)$$

Each component in the Kähler potential is given by

$$K_{\text{Pol}}^{(\text{eff})} = c_0^\dagger Z + c_0 Z^\dagger + |Z|^2 - \frac{1}{12} \frac{m_z^2}{m_{3/2}^2 M_{\text{pl}}^2} |Z|^4 + \dots, \quad (43)$$

$$\begin{aligned} K_{\text{inf}} = & |\Psi|^2 + |S|^2 + |X|^2 + |Y|^2 + |N|^2 \\ & + (1+k)|S|^2|X|^2 + (1-k')|\Psi|^2|X|^2 \\ & - \frac{k_1}{4}|X|^4 - k_2|X|^2|Y|^2 - k_3|X|^2|N|^2 + \dots, \end{aligned} \quad (44)$$

$$K_{\text{int}} = |\Psi|^2(c_1^\dagger Z + c_1 Z^\dagger) + \dots, \quad (45)$$

where Z, Ψ, S, X, Y and N are chiral superfields and k, k', k_1, k_2 and k_3 are positive constants. Here N denotes the right-handed neutrino and Z the SUSY breaking field which would have large mass $m_Z \gg m_{3/2}$ by the fourth operator in Eq.(43) produced by the strong dynamics. The ellipses denote higher dimensional operators, which may be neglected during the inflation and the following reheating era.

The operators in the superpotential are given by

$$W_{\text{Pol}}^{(\text{eff})} = \sqrt{3}m_{3/2}M_{\text{pl}}Z, \quad (46)$$

$$W_{\text{inf}} = X \left(v^2 - \frac{\lambda}{2} \Psi^2 \right) + Y(A\sqrt{\lambda}v - gS)\Psi + \frac{h}{2}\Psi N^2, \quad (47)$$

where constants v, λ, A, g and h can be chosen to be real and positive by field redefinition without loss of generality ¹⁷.

¹⁶ Here we dismiss superpotential interaction terms like the third term in Eq.(19), since the effects of these operators can be absorbed into the definition of c_1 in Eq.(45). See Eq.(20) for this redefinition.

¹⁷ We note that the Lagrangian has $U(1)_R \times Z_2$ symmetry and the superpotential can include other operators allowed by this symmetry. However, we dismiss these operators in this paper, since our attention is not to produce a complete model in particle physics but to show the existence of a model satisfying the cosmological constraints.

Then, the scalar potential in SUGRA is approximately given by

$$\begin{aligned}
V \simeq & \left| v^2 - \frac{\lambda}{2} \Psi^2 \right|^2 + |A\sqrt{\lambda}v - gS|^2 |\Psi|^2 \\
& - \frac{k}{M_{\text{pl}}^2} v^4 |S|^2 + \frac{k'}{M_{\text{pl}}^2} v^4 |\Psi|^2 \\
& + \left| \lambda X \Psi - Y(A\sqrt{\lambda}v - gS) - \frac{h}{2} N^2 \right|^2 + g^2 |Y|^2 |\Psi|^2 + h^2 |\Psi|^2 |N|^2 \\
& + \frac{k_1}{M_{\text{pl}}^2} v^4 |X|^2 + \frac{1+k_2}{M_{\text{pl}}^2} v^4 |Y|^2 + \frac{1+k_3}{M_{\text{pl}}^2} v^4 |N|^2 + \dots,
\end{aligned} \tag{48}$$

where the terms in the second and fourth lines are the Hubble mass terms induced by the SUGRA contributions. The ellipses denote the other SUGRA contributions which are not important in the following discussions. In this potential, all the scalar fields except for $\psi \equiv \sqrt{2} \text{Re } \Psi$ and $s \equiv \sqrt{2} \text{Re } S$ remain in the origin during the inflation and the following coherent oscillation era, if all the scalar component of the chiral super multiplets are set to the origin before the primordial inflation¹⁸. Thus we can use this model as a realization of the potential Eq.(29).

The energy of the universe during the coherent oscillation era is dominated by the waterfall field, whose initial amplitude and the mass are given by

$$\langle \psi \rangle = \frac{2}{\sqrt{\lambda}} v \simeq 1.7 \times 10^{13} \text{GeV} \times \frac{A-1}{g}, \tag{49}$$

$$m_\psi = \lambda \langle \psi \rangle \simeq 1.7 \times 10^8 \text{GeV} \times \frac{A-1}{g} \left(\frac{\lambda}{10^{-5}} \right), \tag{50}$$

if $T_R \simeq 10^6 \text{GeV}$ is realized. After the oscillation, the waterfall field mainly decays into two right-handed neutrinos, if an inequality $m_\psi > 2m_N = 2h\langle \psi \rangle$ is satisfied.

The decay width is approximately given by

$$\Gamma_\psi \simeq \frac{h^2}{16\pi} m_\psi. \tag{51}$$

From this decay width the reheating temperature is approximately given by

$$T_R \simeq \left(\frac{10}{g_* \pi^2} M_{\text{pl}}^2 \Gamma_\psi^2 \right)^{\frac{1}{4}} \simeq 1.1 \times 10^6 \text{GeV} \times \frac{3h}{\lambda} \left(\frac{A-1}{g} \right)^{\frac{1}{2}} \left(\frac{\lambda}{6 \times 10^{-6}} \right)^{\frac{3}{2}}, \tag{52}$$

where $g_* = 228.75$ is the massless degrees of freedom in the MSSM.

¹⁸ Such a situation can be realized by thermal effects or another inflation before the primordial inflation.

The baryon asymmetry is produced by the decay of these right-handed neutrinos as:

$$\begin{aligned}\frac{n_B}{s} &\simeq 8.2 \times 10^{-11} \left(\frac{T_R}{10^6 \text{GeV}} \right) \left(\frac{2m_N}{m_\psi} \right) \left(\frac{m_{\nu_3}}{0.05 \text{eV}} \right) \frac{1}{\sin^2 \beta} \delta_{\text{eff}} \\ &\simeq 8.2 \times 10^{-11} \left(\frac{T_R}{10^6 \text{GeV}} \right) \left(\frac{2h}{\lambda} \right) \left(\frac{m_{\nu_3}}{0.05 \text{eV}} \right) \frac{1}{\sin^2 \beta} \delta_{\text{eff}},\end{aligned}\quad (53)$$

which should be $n_B/s \simeq 8.7 \times 10^{-11}$ for the successful nucleosynthesis. Here m_{ν_3} denotes the mass of the heaviest (active) neutrino, which is generated by the see-saw mechanism [31]. The phase δ_{eff} is the effective CP phase defined in [33] and $\tan \beta$ is the ratio of the vacuum expectation values of the up- and down-type Higgs bosons in the MSSM. Thus we have found that the successful nucleosynthesis can be realized when the following conditions are satisfied ¹⁹:

$$\lambda \simeq 6 \times 10^{-6} \times \left(\frac{g}{A-1} \right)^{\frac{1}{3}}, \quad (54)$$

$$h \simeq 2 \times 10^{-6} \times \left(\frac{g}{A-1} \right)^{\frac{1}{3}}, \quad (55)$$

where we have assumed $m_\psi/m_N = \lambda/h = 3$ for the brevity.

From the above discussions, we can represent H_{inf} , m_ψ and $Y_{3/2}^{\text{inf}}$ in terms of g , A and C by using the observed baryon asymmetry and the COBE normalization as:

$$H_{\text{inf}} \simeq \frac{\sqrt{V}}{\sqrt{3}M_{\text{pl}}} \simeq \frac{v^2}{\sqrt{3}M_{\text{pl}}} \simeq 100 \text{ GeV} \left(\frac{A-1}{g} \right)^{5/3}, \quad (56)$$

$$m_\psi = \sqrt{\lambda}v \simeq 1.0 \times 10^8 \text{ GeV} \left(\frac{A-1}{g} \right)^{2/3}, \quad (57)$$

$$Y_{3/2}^{\text{inf}} \simeq 2 \frac{\Gamma_{3/2}}{\Gamma_\psi} \frac{3}{4} \frac{T_R}{m_\psi} \simeq 6.5 \times 10^{-13} \left(\frac{A-1}{g} \right)^{14/3} C^2. \quad (58)$$

In Fig.2, we have plotted the yield of the gravitinos for $C = 1$. From this figure and the equations above, we see that this inverted Hybrid inflation model can sufficiently suppress gravitinos produced through all processes, simultaneously producing sufficient fluctuation of CMB and the baryon asymmetry. As a conclusion of this section, we have confirmed that the inverted hybrid inflation model is consistent with the gravity mediation scenario.

¹⁹ Note that the constraint Eq.(27) also must be satisfied.

Figure 2: The gravitino yield in the inverted hybrid inflation model is plotted. The (red) solid line denote $Y_{3/2} = 10^{-16}$, (green) dashed line $Y_{3/2} = 10^{-14}$ and (blue) dash-dotted line $Y_{3/2} = 10^{-12}$. In all the parameter region of this figure, the WMAP observation is reproduced and the sufficient baryon asymmetry is produced.

4 Summary

The supersymmetric standard model is very attractive, since it can explain the large hierarchy and the observed dark matter density. However, it was discovered that the supersymmetric standard model is not consistent with most of the inflation models, if the SUSY breaking is mediated by Planck suppressed operators. Under these circumstances, we have searched for successful inflation models in this paper.

Examining the gravitino production processes (i), (ii), (iii) and (iv) in the gravity mediation scenario, we have found that successful inflation models must have sufficiently low height of the potential, an appropriate reheating temperature, and a small mass and a small VEV of the inflaton at the true vacuum. Studying these requirements and the WMAP results, we have found that a particular inverted hybrid inflation model is an example of such successful inflation models. Furthermore, we have found that this inflation model accommodates the see-saw mechanism and produces a sufficient baryon asymmetry by the leptogenesis mechanism. We consider that appropriate inflation models including this inverted hybrid inflation model will become interesting, when the gravity mediation scenario is confirmed in the future accelerator experiments.
